ProMik GmbH is a company which provides different programming solutions of microcontrollers by deployment of programmers which are able to perform inter circuit tests (ICT). Such a microcontroller can consist of the Joint Test Action Group (**JTAG**) device which further provides the possibility of performing boundary scan tests with it. A boundary scan description language (BSDL) file contains all information of the boundary scan compatible pins of one JTAG device. Now to be able to communicate and perform such tests there is the serial vector format (SVF) available which contains a few commands as test data input (TDI) and test data output (TDO) to apply them on the pins of interface. The open database (ODB)++ format is a computer aided design based container format which holds all information about an electric circuit diagram containing its all comonents and information about the connected nets. The PCB-Investigator is a third party tool for reading and analyzing purposes of much project formats. Finally the Google Remote Procedure Call (GRPC) is a protocol for exchanging data in serialized form over the network by using a interface description language for auto generating code which could be used independently on the used programming language
